

Assignment 2 – Week 2

This assignment is based on lecture 2 (chapters 4 & 5).

- Submit your *own work* on time. No credit will be given if the assignment is submitted after the due date.
 - Note that the completed assignment should be submitted in .doc, .docx, .rtf or .pdf format only.
 - If you think that your answer needs explanation to get credit then please write it down.
 - You are encouraged to discuss these questions in the Sakai forum.
-

(1) A relational database consists of a collection of

- A. Tables
- B. Fields
- C. Records
- D. Keys

ANS: A

(2) A _____ in a table represents a relationship among a set of values.

- A. Column
- B. Key
- C. Row
- D. Entry

ANS: C

(3) For each attribute of a relation, there is a set of permitted values, called the _____ of that attribute.

- A. Domain
- B. Relation
- C. Set
- D. Schema

ANS: A

(4) Course(course_id, sec_id, semester)

Here the course_id, sec_id and semester are _____ and course is a _____ .

- A. Relations, Attribute
- B. Attributes, Relation
- C. Tuple, Relation
- D. Tuple, Attributes

ANS: B

(5) Department (dept_name, building, budget) and

Employee (emp_id , name, dept_name, salary)

Here the dept_name attribute appears in both the relations.

Using the common attributes in relation schema is one way of relating _____ relations.

- A. Attributes of common
- B. Tuple of common

- C. Tuple of distinct
- D. Attributes of distinct

ANS: D

(6) Student (ID, name, dept_name, tot_pts)

In this query which attribute form the primary key?

- A. name
- B. dept_name
- C. tot_pts
- D. ID

ANS: D

(7) The___ operation allows the combining of two relations by merging pairs of tuples, one from each relation, into a single tuple.

- A. Select
- B. Join
- C. Union
- D. Intersection

ANS: B

(8) Discuss the differences between the five Join operations: Theta join, Equijoin, Natural join, Outer join (left), and Semijoin. Example of each is appreciated.

ANS:

- Theta join is combines tuples from 2 relations using a general condition.

SELECT * FROM Student S, Population P WHERE S.height > P.medium_height ;

- Equijoin is a special case of theta join where condition is “=”.

SELECT * FROM Student S, Population P WHERE S.height = P.medium_height ;

- Natural join automatically joins 2 relations on all attributes with the same name and removes duplicate columns.

SELECT * FROM Student NATURAL JOIN Population;

- Outer join returns all tuples from left relation and match tuples from the right. If no match, fill with null.

SELECT * FROM Student LEFT OUTER JOIN Population ON Student.height = Population.medium_height;

- Semijoin returns tuples from one relation, that have matching tuples in the other, but no combining them.

SELECT * FROM Student WHERE address IN (SELECT address from Population);

(9) A relational database contains details about journeys from Chicago to a variety of destinations and contains the following relations:

Operator (opCode, opName)
Journey (opCode, destCode, price)
Destination (destCode, destName, distance)

Each operator is assigned a unique code (opCode) and the relation *Operator* records the association between this code and the Operator's name (opName).

Each destination has a unique code (destCode) and the relation *Destination* records the association between this code and the destination name (destName), and the distance of the destination from Chicago.

The relation *Journey* records the price of an adult fare from Chicago to the given destination by a specified operator; several operators may operate over the same route.

Formulate the following queries using relational algebra.

- 1) List the details of journeys less than \$100.
- 2) List the names of all destinations.
- 3) Find the names of all destinations within 20 miles.
- 4) List the names of all operators with at least one journey priced at under \$5.
- 5) List the names of all operators and prices of journeys to 'Boston'.

ANS: 1. $\sigma \text{ price} < 100$ (*Journey*)
2. $\pi \text{ destName}$ (*Destination*)
3. $\pi \text{ destName} (\sigma \text{ distance} \leq 20)$
4. $\pi \text{ opName} (\text{Operator} \bowtie \sigma \text{ price} < 5 (\text{Journey}))$
5. $\pi \text{ opName, price} (\text{Operator} \bowtie \text{Journey} \bowtie \sigma \text{ destName} = \text{'Boston'} (\text{Destination}))$

(10) Solve Q 5.8 (a-d) on page no. 130 from the course text book (5th edition).

a) $\pi_{\text{hotelNo}} (\sigma_{\text{price} > 50} (\text{Room}))$

ANS: Return the hotelNo value from Room table where price > 50

b) $\sigma_{\text{Hotel.hotelNo} = \text{Room.hotelNo}} (\text{Hotel} \times \text{Room})$

ANS: Join Hotel and Room table on hotelNo attribute

c) $\pi_{\text{hotelName}} (\text{Hotel} \bowtie_{\text{Hotel.hotelNo} = \text{Room.hotelNo}} (\sigma_{\text{price} > 50} (\text{Room})))$

ANS: Return hotelName for hotels that have a room with price > 50

d) $\text{Guest} \bowtie (\sigma_{\text{dateTo} \geq \text{'1-Jan-2007'}} (\text{Booking}))$

ANS: Return Guest records for these guests who have bookings that end on after 1-jan-2007
